Undecidability of accordance for open systems with unbounded message queues

Richard Müller, Christian Stahl, Walter Vogler

Abstract
We study asynchronously communicating open systems modeled as Petri nets with an interface. An accordance preorder describes when one open system can be safely replaced by another open system without affecting some behavioral property of the overall system. Although accordance is decidable for several behavioral properties if we assume a previously known bound on the maximal number of pending messages, we show that it is not decidable without this assumption.

Keywords: Petri nets, open nets, accordance preorder, theory of computation

1. Introduction

Today’s software systems are complex distributed systems that are composed of less complex open systems. In this paper, we focus on stateful open systems that have a well-defined interface and communicate with each other via asynchronous message passing. Service-oriented systems like Web-service applications [1, 2] and systems based on wireless network technologies like wireless sensor networks [3], medical systems, transportation systems, or online gaming are examples of such distributed systems.

During system evolution, often an open system is replaced by another one—for example, when new features have been implemented or bugs have been fixed. To describe what replacements are acceptable a refinement preorder is introduced, required, which can be formalized as an accordance preorder. An accordance preorder indicates whether we can safely replace an open system by another one without affecting some relevant behavioral property of the overall system.

Here, we consider open systems on an abstract level—for example, abstracting from message contents—and model them with open (Petri) nets. Decision procedures for accordance exist for deadlock freedom [4] and responsiveness [5] (i.e., the perpetual possibility to reach a final state).

We continue with some background information on Petri nets and accordance in Sect. 2. In Sect. 3, we prove the undecidability of accordance for deadlock freedom. We lift this result to accordance for responsiveness in Sect. 4. Section 5 contains the undecidability result of accordance for weak termination, and Section 6 finishes with a discussion of related work.

2. Preliminaries

In this section, our presentation largely follows [6, 7]. For two sets $A$ and $B$, let $A \uplus B$ denote the disjoint union; writing $A \uplus B$ implies that $A$ and $B$ are implicitly assumed to be disjoint. Let $\mathbb{N}$ ($\mathbb{N}_+$) denote the natural numbers (excluding 0). In this paper, we use place/transition Petri nets extended with a set of final markings and either transition labels or interface places.

Definition 1 (net). A net $N = (P,T,F,m_N,\Omega)$ consists of a finite set $P$ of places, a finite set $T$ of transitions such that $P$ and $T$ are disjoint, a flow relation $F \subseteq (P \times T) \uplus (T \times P)$, an initial marking $m_N$, where a marking is a multiset $m : P \rightarrow \mathbb{N}$, and a set $\Omega$ of final markings.

Where needed (Definitions 4, 5), we implicitly extend a marking $m$ to additional places, for which $m$ returns 0.

Introducing a net $N$ also implicitly introduces its components $P,T,F,m_N$, and $\Omega$—and similarly for nets $N_1$, $N_2$.

Definition 2 (labeled net). A labeled net $N = (P,T,F,m_N,\Omega,\Sigma_{in},\Sigma_{out},l)$ is a net $(P,T,F,m_N,\Omega)$ together with an alphabet $\Sigma = \Sigma_{in} \uplus \Sigma_{out}$ of input actions $\Sigma_{in}$ and

Preprint submitted to Elsevier September 8, 2013
output actions $\Sigma_{out}$ and a labeling function $l : T \rightarrow \Sigma \uplus \{\tau\}$, where $\tau$ represents an invisible, internal action. Two labeled nets are action-equivalent if they have the same sets of input and of output actions.

Graphically, a circle represents a place, a box represents a transition, and the directed arcs between places and transitions represent the flow relation. A marking is a distribution of tokens over the places. Graphically, a black dot represents a token. Transition labels are written into the respective boxes.

Let $x \in P \uplus T$ be a node of a net $N$. As usual, $^*x = \{y \mid (y,x) \in F\}$ denotes the preset of $x$ and $x^* = \{y \mid (x,y) \in F\}$ the postset of $x$. A transition $t \in T$ is enabled at a marking $m$, denoted by $m \xrightarrow{t}$, if for all $p \in ^*t$, $m(p) > 0$. If $t$ is enabled at $m$, it can fire, thereby changing the current marking $m$ to the marking $m' = m - ^*t + t^*$ (here, we interpret the pre- and the postset as multisets). The firing of $t$ is denoted by $m \xrightarrow{t} m'$; that is, $t$ is enabled at $m$ and firing it results in $m'$. For a transition sequence $v = t_1 \ldots t_k$, we write $m_1 \xrightarrow{v} m_k$ when $m_1 \xrightarrow{t_1} \ldots \xrightarrow{t_k} m_k$ and refer to it as a run of $N$. A marking $m'$ is reachable from a marking $m$ if there exists a (possibly empty) run $v$ with $m \xrightarrow{v} m'$. A marking $m'$ is reachable if it is reachable from the initial marking. In the case of labeled nets, we lift runs to actions: If $m_1 \xrightarrow{v} m_k$ and $w$ is obtained from $v$ by replacing each transition with its label and removing all $\tau$ labels, we write $m_1 \xrightarrow{\tau w} m_k$ and refer to $w$ as a trace if $m_1 = m_N$. The language $L(N)$ is the set of all traces of $N$.

For two action-equivalent labeled nets $N_1$ and $N_2$, a relation $\rho \subseteq N_1^2 \times N_2^2$ is a bisimulation if for all $(m_1,m_2) \in \rho$: (1) if $m_1 \xrightarrow{t_1} m_1'$ in $N_1$, there exist $t_2$ and $m_2'$ such that $m_2 \xrightarrow{t_2} m_2'$ in $N_2$, $t_1(t_2) = l_2(t_2)$, and $(m_1',m_2') \in \rho$; and (2) if $m_2 \xrightarrow{t_2} m_2'$ in $N_2$, there exist $t_1$ and $m_1'$ such that $m_1 \xrightarrow{t_1} m_1'$ in $N_1$, $t_1(t_2) = l_2(t_2)$, and $(m_1',m_2') \in \rho$. The labeled nets $N_1$ and $N_2$ are bisimilar if there exists a bisimulation relating their initial markings $m_{N_1}$ and $m_{N_2}$.

As system model, we consider open nets. An open net extends a net by an asynchronous interface consisting of two disjoint sets of input and output places, which correspond to input and output channels. In the initial marking and the final markings, interface places are not marked. An input place has an empty preset, and an output place has an empty postset.

**Definition 3** (open net). An open net $N$ is a tuple $(P,T,F,m_N,I,O,\Omega)$ where $(P \uplus I \uplus O,T,F,m_N,\Omega)$ is a net, $m_N(p) = 0 = m(p)$ for all $p \in I \uplus O$ and $m \in \Omega$, $^*p = \emptyset$ for all input places $p \in I$, $p^* = \emptyset$ for all output places $p \in O$, and set $I = \emptyset$ if and only if set $O = \emptyset$.

If $I = O = \emptyset$, then $N$ is a closed net. Two open nets are interface-equivalent if they have the same sets of input and of output places.

Graphically, we represent an open net like a net with a dashed frame around it. The interface places are positioned on the frame.

For the composition of open nets, we assume that the sets of transitions are disjoint and that no internal place of an open net is a place of any other open net. In contrast, the interfaces intentionally overlap. We require that all communication is bilateral and directed; that is, every shared place $p$ has only one open net that sends into $p$ and one open net that receives from $p$. In addition, we require that either all interface places are shared or there is at least one input and one output place which are not shared. We refer to open nets that fulfill these conditions as composable. We compose such open nets by merging shared interface places and turning them into internal places. The definition of composable thereby guarantees that an open net composition is again an open net (which is possibly closed).

**Definition 4** (open net composition). Two open nets $N_1$ and $N_2$ are composable if $(P_1 \uplus T_1 \uplus I_1 \uplus O_1) \cap (P_2 \uplus T_2 \uplus I_2 \uplus O_2) = (I_1 \cap O_2) \uplus (I_2 \cap O_1)$, and $(I_1 \uplus I_2) \setminus (O_1 \uplus O_2)$ and $(O_1 \uplus O_2) \setminus (I_1 \uplus I_2)$ are both either empty or nonempty. The composition of such open nets is the open net $N_1 \uplus N_2 = (P,T,F,m_N,I,O,\Omega)$ where $P = P_1 \uplus P_2 \uplus (I_1 \cap O_2) \uplus (I_2 \cap O_1)$, $T = T_1 \uplus T_2$, $F = F_1 \uplus F_2$, $m_N = m_{N_1} + m_{N_2}$, $I = (I_1 \uplus I_2) \setminus (O_1 \uplus O_2)$, $O = (O_1 \uplus O_2) \setminus (I_1 \uplus I_2)$, and $\Omega = \{m_1 + m_2 \mid m_1 \in \Omega_1, m_2 \in \Omega_2\}$.

To give an open net $N$ a trace-based semantics, we consider its environment $env(N)$, which we define similarly to Vogler [9]. The net $env(N)$ can be constructed from $N$ by adding to each interface place $p \in I (p \in O)$ a $p$-labeled transition $p$ in $env(N)$ and renaming the place $p$ to $p^i$ ($p^o$). Intuitively, one can understand the construction as translating the asynchronous interface of $N$ into a buffered synchronous interface (with unbounded buffers) described by the transition labels of $env(N)$.

**Definition 5** (open net environment). The environment of an open net $N$ is the labeled net $env(N) = (P \uplus P^I \uplus P^O,T \uplus I \uplus O,F',m_N,\Omega,I,O)', where

- $P^I = \{p^i \mid p \in I\}$,
  \[ P^O = \{p^o \mid p \in O\}, \]
- $F' = ((P \uplus T) \times (T \uplus P)) \uplus F$ \uplus \{ $(p,t)$ \mid $p \in I, t \in T, (p,t) \in F$ \}
  \uplus \{ $(t,p^i)$ \mid $p \in I, t \in T, (t,p) \in F$ \}
  \uplus \{ $(p^o,p) \mid p \in O$ \}
  \uplus \{ $(p^o,p^o) \mid p \in I$ \}, and
  \[ I'(t) = \begin{cases} \tau, & t \in T \\ t, & t \in I \uplus O \end{cases} \]

Convention: Throughout the paper, each trace set and semantics for labeled nets is implicitly extended to any open net $N$ via $env(N)$—for example, the language of $N$ is defined as $L(N) = L(env(N))$. 

In this paper, we consider five behavioral properties on the closed composition of two open nets: deadlock freedom with and without final markings, responsiveness with and without final markings, and weak termination.

Definition 6 (behavioral properties). Let $N_1$ and $N_2$ be composable open nets. A marking $m$ of $N_1 \oplus N_2$ is dead if no transition is enabled at $m$, and $f$-dead if additionally $m \notin \Omega_{N_1 \oplus N_2}$. Marking $m$ is responsive if we can reach from $m$ a marking that enables a transition $t$ with $t^* \cap (O_1 \oplus O_2) \neq \emptyset$; it is weakly terminating if we can reach a final marking of $N_1 \oplus N_2$ from $m$; and $m$ is $f$-responsive if $m$ is responsive or weakly terminating.

The open nets $N_1$ and $N_2$ together are deadlock free ($f$-deadlock free) if their composition $N_1 \oplus N_2$ is a closed net and no reachable marking of $N_1 \oplus N_2$ is dead ($f$-dead). $N_1$ and $N_2$ are responsive ($f$-responsive, weakly terminating) if their composition $N_1 \oplus N_2$ is a closed net and every reachable marking of $N_1 \oplus N_2$ is responsive ($f$-responsive, weakly terminating).

Based on a behavioral property, we define a controller $C$ of an open net $N$ such that $N$ and $C$ have that property.

Definition 7 (controller). An open net $N$ is a $f$-controller $(\text{df}-, r-, \text{fr}-, \text{wt}-, \text{controller})$ of an open net $N$ if $N$ and $C$ are deadlock free ($f$-deadlock free, responsive, $f$-responsive, weakly terminating).

If the controllers of an open net are a superset of the controllers of another open net, then the first open net is a refinement of the second; intuitively, we can safely replace the second open system by the first one without affecting the behavioral property of the overall system. We refer to the resulting refinement relation as accordance, which gives a necessary requirement for a refinement. As the accordance preorder for ($f$-)responsiveness is not compositional [5], we also define the coarsest precongruence contained in the respective preorder.

Definition 8 (accordance). Let $x \in \{\text{df}, \text{df}, r, \text{fr}, \text{wt}\}$. For interface-equivalent open nets Impl and Spec, Impl $x$-accords with Spec if for all open nets $C$ the following holds: If $C$ is an $x$-controller of Spec, then $C$ is an $x$-controller of Impl. Let $\subseteq^{\text{fr}}_{\text{acc}}$ denote the coarsest precongruence contained in $r$-accordance ($fr$-accordance).

3. Undecidability of $df$- and $fdf$-accordance

We prove $df$- and $fdf$-accordance to be undecidable by reducing both to the halting problem of Minsky’s counter machines [10]. For the reduction, we use our trace-based characterization of $df$- and $fdf$-accordance [7], which demands specific language inclusions.

Definition 9 (stopdead-semantics for deadlock freedom). Let $N$ be a labeled net. A marking $m$ of $N$ is a stop except for inputs if for all $t \in T$ with $m \xrightarrow{t} \Sigma_m$ holds: $l(t) \in \Sigma_m$; it is dead except for inputs if additionally $m \notin \Omega$.

The stopdead-semantics of $N$ is defined by the sets of traces $\text{stop}(N) = \{ w \mid m_N \xrightarrow{w} m \land m \text{ is a stop except for inputs} \}$ and $\text{dead}(N) = \{ w \mid m_N \xrightarrow{w} m \land m \text{ is dead except for inputs} \}$.

Theorem 10 ($df$- and $fdf$-accordance characterization [7]). For two interface-equivalent open nets Impl and Spec, the following holds: (1) Impl $df$-accords with Spec iff $\text{stop}(\text{Impl}) \subseteq \text{stop}(\text{Spec})$. (2) Impl $fdf$-accords with Spec iff $\text{stop}(\text{Impl}) \subseteq \text{stop}(\text{Spec})$ and $\text{dead(Impl)} \subseteq \text{dead(Spec)}$.

We define a counter machine as in [10].

Definition 11 (counter machine). Let $n, m \in \mathbb{N}_+$. An $n$-counter machine $C$ with nonnegative counters $c_1, \ldots, c_m$ is a program consisting of $n$ commands

\[
1 : \text{CMD}_1; 2 : \text{CMD}_2; \ldots; n : \text{CMD}_n
\]

where $\text{CMD}_n$ is a $\text{HALT}$-command and the commands $\text{CMD}_1, \ldots, \text{CMD}_{n-1}$ are of the following two types (where $1 \leq k, k_1, k_2, n, 1 \leq j \leq m$):

Type 1: $c_j := c_j + 1$; goto $k$

Type 2: if $c_1 = 0$ then goto $k_1$ else ($c_j := c_j - 1$; goto $k_2$)

Define the set $\text{BS}(C)$ of branching states of $C$ as $\text{BS}(C) = \{ i \in \mathbb{N}_+ \mid \text{CMD}_i \text{ is of type 2} \}$.

As a running example, consider the counter machine $\text{ADD}$ in Alg. 1. $\text{ADD}$ has two counters $c_1$ and $c_2$, and consists of three commands: one of each type, and the $\text{HALT}$-command. It expects two given integers $x_1$ and $x_2$ as inputs, and returns their sum $x_1 + x_2$ stored in the counter $c_2$. The branching states of $\text{ADD}$ are $\text{BS}(\text{ADD}) = \{1\}$, and obviously $\text{ADD}$ halts on any inputs.

Algorithm 1: The 2-counter machine $\text{ADD}$ for adding two integers $x_1$ and $x_2$.

We describe three labeled net patterns—one pattern for each CMD-type and an auxiliary notion of a “definitely cheating” pattern—which we use to simulate a counter machine. These patterns are an extension of the “Jančar-Pattern” [11]. For each transition $t$ of the original pattern, we add two transitions and two places controlling $t$’s firing. In addition, we shift the label from $t$ to the newly introduced transitions, and label $t$ with $\tau$. The patterns are illustrated in Fig. 1.

Definition 12 (basic net). Let $C$ be a counter machine with $m$ counters and $n$ commands. The basic net net$(C)$ of $C$ is a labeled net constructed as follows (assuming $1 \leq k, k_1, k_2 \leq n, 1 \leq j \leq m$):
1. Let \( c_1, \ldots, c_m \) (the counter part) and \( s_1, \ldots, s_n \) (the state part) be places of \( \text{net}(C) \).

2. For \( i = 1, \ldots, n-1 \) add new transitions and arcs depending on the type of CMD:
   
   **type 1**: Add places \( w_i, w_i' \), transitions \( t_i, v_i, v_i' \), and arcs \( (v_i, u_i), (u_i, t_i), (t_i, v_i'), (w_i', v_i'), (s_i, t_i), (t_i, s_k) \), and \( (t_i, c_j) \). For the labeling, we set \( l(v_i) = l(v_i') = v'_i \), and \( l(t_i) = \tau \).
   
   **type 2**: Add places \( y_i, y_i', m_i, m_i' \), transitions \( t_i^m, z_i, z_i' \) (to simulate the case in which counter \( c_j \) is zero) and \( t_i^N, n_i, n_i' \) (to simulate the case in which counter \( c_j \) is not empty), and arcs \( (z_i, y_i), (y_i, t_i^m), (t_i^m, y_i'), (y_i', z_i'), (n_i, m_i), (m_i, t_i^N), (t_i^N, m_i'), (m_i', n_i'), (s_i, t_i^m), (t_i^m, s_k), (s_i, t_i^N), (c_j, t_i^m), (t_i^m, c_j) \). For the labeling, we set \( l(z_i) = z_i, l(z_i') = z_i', l(n_i) = n_i, l(n_i') = n_i' \), and \( l(t_i^N) = l(t_i^N) = \tau \).

3. Let the initial marking put just one token on \( s_1 \), and let \( \emptyset \) be the set of final markings of \( \text{net}(C) \).

4. Let every unprimed transition label of \( \text{net}(C) \) (other than \( \tau \)) be an input action, and let every primed transition label of \( \text{net}(C) \) be an output action.

Adding a dc-pattern (dc for “definitely cheating”) to \( \text{net}(C) \) for \( i \in BS(C) \) means adding a \( \tau \)-labeled transition \( t_i^C \) (a dc-transition) and arcs \( (y_i, t_i^C), (t_i^C, y_i'), (s_i, t_i^C), (t_i^C, s_k), (c_j, t_i^C), (t_i^C, c_j) \). (Note that \( t_i^C \) is a copy of \( t_i^C \) with additional arcs to/from \( c_j \).)

For the counter machine \text{ADD} from Alg. 1 Fig. 2 depicts the basic net \( \text{net}(\text{ADD}) \). It consists of one pattern of type 1 (transitions \( t_2, v_2, v_2' \)) and one pattern of type 2 (transitions \( t_2^m, t_2^r, n_1, n_1', z_1, z_1' \)). The counters \( c_1 \) and \( c_2 \) are modeled by the places \( c_1 \) and \( c_2 \), and the current state of \( \text{ADD} \) is modeled by marking one of the places \( s_1, s_2, s_3 \). The input actions of \( \text{net}(\text{ADD}) \) are \( \{n_1, z_1, v_2\} \), and the output actions are \( \{n_1', z_1', v_2'\} \).

For any counter machine with counters \( c_1, \ldots, c_m \) and for any input values \( x_1, \ldots, x_m \), we can “simulate” \( C \) with \( \text{net}(C) \) by adding \( x_j \) tokens to the initial marking of place \( c_j \) (\( 1 \leq j \leq m \)). However, it is possible to “cheat” in the pattern of type 2 (see Fig. 1b), i.e., transition \( t_i^z \) fires although the respective place \( c_j \) is not empty. Also notice that firing a dc-transition has the same effect as firing the respective transition \( t_i^z \).

The construction of \( \text{net}(C) \) applies to any counter machine, but we will consider a 2-counter machine \( C \) in the following, because already for two counters the halting problem is undecidable [10].

**Theorem 13** (halting problem [10]). It is undecidable whether a given 2-counter machine halts on given inputs.

The following lemma relates the halting problem for 2-counter machines to the inclusion of the stop-languages of two constructed labeled nets. We follow the proof strategy from [11]: For a 2-counter machine \( C \) and given input values \( x_1 \) and \( x_2 \), we construct two labeled nets \( N_1 \) and \( N_2 \) which are modifications of \( \text{net}(C) \) simulating \( C \). The construction of \( N_1 \) and \( N_2 \) ensures that the only way to exhibit the non-inclusion is to simulate \( C \) without cheating and to terminate—which is possible if and only if \( C \) halts for \( x_1 \) and \( x_2 \).

**Lemma 14.** Let \( C \) be a 2-counter machine and \( x_1, x_2 \in \mathbb{N} \). We can construct two action-equivalent labeled nets \( N_1 \) and \( N_2 \) (as modifications of \( \text{net}(C) \)) such that the following conditions are equivalent:

1. \( C \) does not halt for the given inputs \( x_1 \) and \( x_2 \).
2. \( N_1 \) and \( N_2 \) are bisimilar.
3. \( \text{stop}(N_1) \subseteq \text{stop}(N_2) \).

**Proof.** We construct \( N_1 \) and \( N_2 \) from \( \text{net}(C) \) and the input values \( x_1 \) and \( x_2 \) in four steps:

1. Take \( \text{net}(C) \) and extend its initial marking by \( x_1 \) tokens in \( c_1 \) and \( x_2 \) tokens in \( c_2 \).
2. Add places \( p, p', e \), transitions \( t_p, t_p', t_e, f \), and arcs \( (p, t_p), (t_p, p), (p', t_p'), (t_p', p') \), \( (p, t_e), (t_e, e) \). Label the transitions \( t_p, t_p', t_e \) and \( t_e \) with \( \tau \), and \( f \) with \( f \). Figure 3 sketches steps one and two for \( \text{ADD} \) with inputs \( x_1 := 1 \) and \( x_2 := 1 \).
3. For each branching state $i \in BS(C)$ that checks counter $c_j$, add two $2$-patterns: the $2$-labeled transitions $t_i^C$, $t_i^{C'}$, and the arcs $(s_i,t_i^C)$, $(s_i,t_i^{C'})$, $(t_i^C,s_i)$, $(t_i^{C'},s_i)$, $(y_i,t_i^C)$, $(y_i,t_i^{C'})$, $(t_i^C,y_i)$, $(t_i^{C'},y_i)$ (i.e., detecting cheating on the zero-branch), $(c_j,t_i^C)$, $(t_i^{C'},c_j)$, $(c_j,t_i^C)$, $(t_i^{C'},c_j)$ (i.e., cheating means $c_j$ is not empty), and $(p,t_i^C)$, $(t_i^C,p)$, $(t_i^{C'},p)$, $(t_i^{C'},p)$ (i.e., detecting cheating means switching the token between $p$ and $p'$). Figure 4 (ignoring the token on place $p$) sketches this step for $ADD$ and $ADD(ADD) = \{1\}$.

4. Take two copies of the arising net. In one copy, put one token in $p$ yielding the labeled net $N_1$. In the other, put one token in $p'$ yielding the labeled net $N_2$. Figures 3b and 3c indicate this for $ADD$, if we ignore the dashed frame.

In every reachable marking, the places $p$ and $p'$ together hold at most one token. As long as place $p$ or $p'$ remains marked, the corresponding marking is not a stop (except for inputs due to $t_2$ and $t_2'$, respectively). The only way to reach a stop except for inputs is to have one token on $p$ and fire $t_e$ and $f$.

(1) implies (2): Assume $C$ does not halt for inputs $x_1$ and $x_2$. Let $D$ be the set of all pairs $(m,n)$ of equal markings $m$ of $N_1$ and $N_2$. Let $M$ be the set of all pairs $(m_1,m_2)$ such that $m_1$ and $m_2$ are reachable by the same correct run in $N_1$ and $N_2$, respectively. A run is correct if it simulates $C$ without cheating, i.e., no $\sigma$-transition fires, and transition $t_i^\sigma$ (for $i \in BS(C)$) fires only if the respective place $c_j$ is empty. We show that $D \cup M$ is a bisimulation; thus, $N_1$ and $N_2$ are bisimilar as $(m_1,m_2) \in M$ by the construction of $N_1$ and $N_2$.

So consider a pair $(m_1,m_2) \in M$. As $m_1$ and $m_2$ is the same correct run $\sigma$ in $N_1$ and $N_2$, respectively, $m_1$ and $m_2$ differ only in the places $p$ and $p'$, i.e., we have $m_1(p) = 1$, $m_1(p') = 0$, and $m_2(p) = 0$, $m_2(p') = 1$, w.l.o.g. Thus, every transition, except $t_e$ and the $\sigma$-transitions, is enabled in $m_1$ in $N_1$ if and only if is enabled at $m_2$ in $N_2$. Transition $t_e$ is never enabled, because $\sigma$ is a correct run, and $C$ does not halt by assumption (i.e., place $s_0$ is never marked). We distinguish two cases:

1. The firing of any transition besides $t_i^\sigma$, $t_i^C$, and $t_i^{C'}$ (for $i \in BS(C)$) at $m_1$ in $N_1$ can be simulated by the firing of the same transition at $m_2$ in $N_2$, and versa. The respective firings lead again to a marking pair in $M$.

2. If cheating is possible in $N_1$ at $m_1$ and $N_1$ fires $t_i^\sigma$, $t_i^C$, or $t_i^{C'}$ with $i \in BS(C)$ when the respective place $c_j$ is not empty, then one transition out of the set $\{t_i^\sigma, t_i^C, t_i^{C'}\}$ can fire in $N_2$ such that both nets have the same marking $m$ (and thus $(m,m) \in D$) afterward. In detail: If $m_1 \xrightarrow{t_i^\sigma} m$ in $N_1$, then $m_2 \xrightarrow{t_i^{C'}} m$ in $N_2$; if $m_1 \xrightarrow{t_i^C} m$ in $N_1$, then $m_2 \xrightarrow{t_i^C} m$ in $N_2$. The same argument applies if cheating is possible in $N_2$: If $m_2 \xrightarrow{t_i^\sigma} m$ in $N_2$, then $m_1 \xrightarrow{t_i^C} m$ in $N_1$; if $m_2 \xrightarrow{t_i^{C'}} m$ in $N_2$, then $m_1 \xrightarrow{t_i^{C'}} m$ in $N_1$.

If $N_1$ and $N_2$ have the same marking (i.e., we have a pair in $D$), then each can simulate the other by firing the same transition, remaining in $D$. Thus, $D \cup M$ is a bisimulation.

(2) implies (3): trivial

(3) implies (1): By contraposition, assume $C$ halts for inputs $x_1$ and $x_2$. Then, we construct a run $m_{N_1} \xrightarrow{t_1} m$ in $N_1$ such that $\sigma$ simulates $C$ correctly (i.e., without cheating) and $m(s_0) = 1$ (i.e., $C$ reaches the HALT command): For each command $CMD_i$ that $C$ performs, we add three transitions to $\sigma$. If $i \notin BS(C)$, we add $t_i, t_i', t_i''$ to $\sigma$. If $i \in BS(C)$, we add $z_i t_i^\sigma z_i'$ (if the respective counter is zero) or $m_i t_i^\sigma n_i$ (otherwise) to $\sigma$. Now the trace $w$ corresponding to the run $\sigma w f$ is a stop-trace of $N_1$, i.e., $w \notin \text{stop}(N_1)$.

To perform the same trace in $N_2$, there is no choice but to perform the same run $\sigma$ (except for possibly firing $t_2$ or $t_2'$ in-between). For instance, to perform action $v_1$, one has to fire transition $v_1$, and to perform action $v_1'$ then one has to fire transitions $t_1 v_1'$. Observe that one cannot fire $t_i^\sigma z_i'$ or $t_i^C z_i'$ to perform action $z_i'$ because the firing of $t_i^\sigma$ is correct at this stage and, thus, the respective counter (and the corresponding place) is empty. However, after $\sigma$ the transition $t_e$ is not enabled in $N_2$, because $p$ is not marked. Thus, $w \notin L(N_2)$, which implies $w \notin \text{stop}(N_2)$. With Lemma 14 we reduce $df$- and $df\alpha$-accordance to the halting problem of a 2-counter machine.

Theorem 15 (undecidability of $df$- and $df\alpha$-accordance). For two interface-equivalent open nets $\text{Impl}$ and $\text{Spec}$, $df$-accordance and $df\alpha$-accordance are undecidable.

Proof. Let $C$ be a 2-counter machine with input values $x_1$ and $x_2$. We construct two interface-equivalent open nets $\text{open}(N_1)$ and $\text{open}(N_2)$ from the labeled nets $N_1$ and $N_2$ from Lemma 14 by removing all transitions $t$ that are not $\tau$-labeled, and interpreting $t$'s preset (postset) as output (input) place. Figures 3b and 3c illustrate $\text{open}(N_1)$ and $\text{open}(N_2)$ for $ADD$, if we ignore all transitions outside the dashed frame. Clearly, $\text{stop}(\text{open}(N_1)) = \text{stop}(N_1)$ and $\text{stop}(\text{open}(N_2)) = \text{stop}(N_2)$. Now assume that $df$-accordance is decidable. Then $\text{open}(N_1)$ $df$-accords with $\text{open}(N_2)$ iff $\text{stop}(\text{open}(N_1)) \subseteq \text{stop}(\text{open}(N_2))$ by Theorem 10 if $C$ does not halt for the given inputs $x_1$ and $x_2$ by Lemma 14. Thus, we can decide the halting problem for 2-counter machines, which is a contradiction to Theorem 13. Therefore, $df\alpha$-accordance is undecidable.

As $df$- and $df\alpha$-accordance coincide for open nets with an empty set of final markings, we conclude the undecidability of $df\alpha$-accordance from the undecidability of $df$-accordance.

4. Undecidability of $r$- and $r\alpha$-accordance

We prove that $r$- and $r\alpha$-accordance and their coarsest precongruences $\equiv_{r,\alpha}$ and $\equiv_{r\alpha,\alpha}$ are undecidable, thereby
following the proof strategy from Sect. 3. As we use the trace-based characterization of r- and fr-accordance from [6], we redefine the stopdead-semantics from Sect. 3 for responsiveness.

**Definition 16 (stopdead-semantics for responsiveness).** Let \( N \) be a labeled net. A marking \( m \) of \( N \) is an r-stop except for inputs if there is no \( o \in \Sigma_{\text{out}} \) such that \( m \xrightarrow{r} m' \); marking \( m \) is r-dead except for inputs if additionally there exists no final marking \( m' \) of \( N \) with \( m \xrightarrow{r} m' \). The responsive stopdead-semantics of a \( N \) is defined by the sets of traces \( \text{rstop}(N) = \{ w \mid m_N \xrightarrow{r} m \land m \text{ is an r-stop except for inputs} \} \) and \( \text{rdead}(N) = \{ w \mid m_N \xrightarrow{r} m \land m \text{ is r-dead except for inputs} \} \).

**Theorem 17 (r- and fr-accordance characterization [6]).** For interface-equivalent open nets \( \text{Impl} \) and \( \text{Spec} \), the following holds: (1) \( \text{Impl} \) r-accords with \( \text{Spec} \) iff \( \text{rstop}(\text{Impl}) \subseteq \text{rstop}(\text{Spec}) \). (2) \( \text{Impl} \) fr-accords with \( \text{Spec} \) iff \( \text{rstop}(\text{Impl}) \subseteq \text{rstop}(\text{Spec}) \) and \( \text{rdead}(\text{Impl}) \subseteq \text{rdead}(\text{Spec}) \).

Similarly to Sect. 3, we reduce r- and fr-accordance to the halting problem of a 2-counter machine.

**Lemma 18.** Let \( C \) be a 2-counter machine and \( x_1, x_2 \in \mathbb{N} \). We can construct two action-equivalent labeled nets \( N_1 \) and \( N_2 \) (as modifications of net(\( C \))) such that the following conditions are equivalent:

1. \( C \) does not halt for the given inputs \( x_1 \) and \( x_2 \).
2. \( N_1 \) and \( N_2 \) are bisimilar.
3. \( \text{rstop}(N_1) \subseteq \text{rstop}(N_2) \).

**Proof.** We construct the two action-equivalent labeled nets \( N_1 \) and \( N_2 \) from \( C \) and the input values \( x_1 \) and \( x_2 \) in the same four steps as in the proof of Lemma 17 with only one modification of step two: We additionally add a place \( o \), a transition \( t_o \), and arcs \( (t_p,o),(t'_p,o) \), and \( (o,t_o) \). Transition \( t_o \) is labeled with the output action \( t_o \).

As long as any of the places \( p, p' \) and \( o \) is marked, the corresponding marking is not an r-stop except for inputs: The transition \( t_o \) is labeled with an output action and may fire. Thus, the only way to reach an r-stop except for inputs is to empty the place \( o \) by firing \( t_o \), and to empty the places \( p, p' \) by firing the transitions \( t_o \) and \( f \). The rest of the proof is analogous to the proof of Lemma 17.

We immediately conclude undecidability of r- and fr-accordance from Lemma 18 and Theorems 17 and 13 with an argument as in the proof of Theorem 15.

**Theorem 19** (undecidability of r and fr-accordance). For two interface-equivalent open nets \( \text{Impl} \) and \( \text{Spec} \), r-accordance and fr-accordance are undecidable.

In the following, we show that also the coarsest precongruence contained in \((f)\)-responsive accordance is undecidable. Here, it is essential that \( \sqsubseteq_{\text{r,acc}} \) and \( \sqsubseteq_{\text{fr,acc}} \) can be characterized using the impossible futures semantics \( F^+(N) \) [9, 12] and a modification \( F^+_r(N) \) of it, as shown in [9]. With this, it is not difficult to prove the following lemma.

**Lemma 20.** For two action-equivalent labeled nets \( N_1 \) and \( N_2 \), the following holds: (1) If \( N_1 \) and \( N_2 \) are bisimilar, then \( N_1 \sqsubseteq_{\text{r,acc}} N_2 \). (2) \( N_1 \sqsubseteq_{\text{r,acc}} N_2 \) implies \( L(N_1) \subseteq L(N_2) \).

With the construction from Lemma 18, we show the undecidability of the coarsest precongruence contained in each preorder.

---

1. For bisimilar nets, even the \( F^+ \)-semantics coincide. If \( N_1 \sqsubseteq_{\text{r,acc}} N_2 \) and \( w \in L(N_1) \) then \( (w,\emptyset) \in F^+(N_1) \), implying \( (w,\emptyset) \in F^+(N_2) \) and thus \( w \in L(N_2) \).
Lemma 21. Let $C$ be a 2-counter machine and $x_1, x_2 \in \mathbb{N}$. We can construct two action-equivalent labeled nets $N_1$ and $N_2$ (without final markings) such that the following conditions are equivalent:

1. $C$ does not halt for the given inputs $x_1$ and $x_2$.
2. $N_1 \sqsubseteq_{fr,acc} N_2$.

Proof. We construct the labeled nets $N_1$ and $N_2$ as in the proof of Lemma 13 (1) implies (2) because $N_1$ and $N_2$ are bisimilar by Lemma 18 which implies $N_1 \sqsubseteq_{fr,acc} N_2$ by Lemma 20(1). (2) implies (1) because if $C$ halts for the inputs $x_1$ and $x_2$, then $L(N_1) \nsubseteq L(N_2)$ as shown in the proof of Lemma 18 and 14. Thus, $N_1 \nsubseteq_{fr,acc} N_2$ by Lemma 20(2).

One can observe that, for open nets without final markings, $\sqsubseteq_{fr,acc}$ and $\sqsubseteq_{fr,acc}$ coincide. With this, we immediately conclude undecidability of $\sqsubseteq_{fr,acc}$ and $\sqsubseteq_{fr,acc}$ from Lemma 21 and Theorem 13 with an argument as in the proof of Theorem 14.

Theorem 22 (undecidability of $\sqsubseteq_{fr,acc}$ and $\sqsubseteq_{fr,acc}$). For two interface-equivalent open nets $\text{Impl}$ and $\text{Spec}$, the precongruences $\sqsubseteq_{fr,acc}$ and $\sqsubseteq_{fr,acc}$ are undecidable.

5. Undecidability of wt-accordance

Finally, we reduce to the decision of wt-accordance the question whether an open net has at least one wt-controller—that is, wt-controllability. As the latter is undecidable, wt-accordance is undecidable, too.

Theorem 23. For two interface-equivalent open nets $\text{Impl}$ and $\text{Spec}$, wt-accordance is undecidable.

Proof. We reduce wt-controllability to wt-accordance. Given an open net $N$, we can construct an interface-equivalent open net $C$ that is not wt-controllable (by putting $\Omega_{C} = \emptyset$). First, if $C$ wt-acords with $N$, then every wt-controller of $N$ is a wt-controller of $C$ and, thus, $N$ is not wt-controllable. Second, if $C$ does not wt-acord with $N$, then $N$ has at least one wt-controller (that is not a wt-controller of $C$) and, thus, $N$ is wt-controllable. Hence, $N$ is wt-controllable iff $C$ does not wt-accord with it.

Bravetti and Zavattaro define the subcontract preorder which preserves weak termination. The model in [14] is a modified version of Milner’s CCS [8], with one unbounded but ordered message queue. In contrast, in our Petri net model, each interface place models an unbounded unordered message queue. Therefore, Theorem 23 does not imply that the subcontract preorder in [14] is undecidable, but we suspect that it is.

6. Related Work and Conclusion

We showed undecidability of accordance for five behavioral properties: deadlock freedom [9] and responsiveness [8]—both with and without final markings—and weak termination [8].

Our proofs mostly work by reduction from the halting problem of 2-counter machines using a variation of the “Jančar-Pattern” [11]. Counter machines and their halting problem were introduced in [10]. The halting problem for counter machines can be used very naturally to show the undecidability of other problems related to Petri nets, such as bisimilarity and language inclusion [11, 15].

The controllability problem is decidable for deadlock freedom and responsiveness: There always exists a trivial controller with an internal loop (deadlock freedom) or a loop in which messages are sent without waiting for an answer (responsiveness). As the corresponding accordance preorders are undecidable, the accordance is a more difficult problem than controllability.

Future work is to investigate accordance for weak termination and bouded communication.
